MDP Application: Supply Chain Inventory Optimization

Our objective is to resolve intricate trade-offs between procurement costs, warehouse space, and customer service levels. This is achieved by employing an infinite-horizon MDP.

MDP formulation

State Space (s)

Real-time inventory levels ranging from 0 to N. Capacity (N) is dynamically set at 1.2x historical peak demand for stability.

Action Space (a)

Discrete order quantities. The model evaluates every possible order size to minimize total expected cost.

Demand Dynamics (ϕ)

Modeled using an empirical distribution from 91,250 records, capturing real demand patterns (seasonality, trends, anomalies)

Reward Function (R)

The reward function is designed to minimize the sum of several key cost components:

- **Purchase Costs (c):** The direct cost associated with acquiring inventory.
- **Holding Costs (h=0.01c):** Costs incurred for storing inventory, calculated as 1% of the purchase cost.
- **Stockout Penalties (p=3×margin):** Significant penalties for unmet demand, set at 3 times the product's margin to prioritize customer service.

Policy Iteration

We applied Policy Iteration to effectively solve the Bellman Optimality Equation:

$$V*(s) = \max_{a \in A(s)} \{R(s,a) + \gamma \sum_{s\prime \in S} P(s\prime \mid s,a) V*(s\prime)\}$$

Experimental Results: The Optimal Inventory Blueprint

Dataset Overview

- **Source**: High-Dimensional Supply Chain Inventory Dataset from Kaggle
- **Size**: 91,250 observations across 15 features
- **SKUs**: 25 unique products analyzed
- **Approach**: Separate MDP solved for each SKU_ID

Policy Convergence

100% of SKUs converged to a **Base-Stock Policy** (Order-up-to S).

For SKU_1, MDP identified that the optimal target stock is **27 units**, whereas the original dataset shows the enterprise was holding **592 units**, reorder **0.**

Strategic Stocking Distribution

- **Mean Target (S):** The average optimal target level across all SKUs was **26.9 units**. This represents approximately 1.3x to 1.5x the average daily demand.
- **Target Variance:** automatically adjusted optimal targets based on SKU "personality"; for example, SKU_11 (high penalty) received a higher buffer S=31, while SKU_29 (low margin) was set to a lean target S=7.

Value Function Analysis (V^*)

Value function shows trade-off between shortage risk (low inventory) and holding costs (high inventory).
